#### ABSTRACT

Cowpea Vigna unguiculata L. Walpers (Fabaceae) is one of the main seed legumes produced and consumed in the world and particularly in West Africa precisely in Mali. In Mali, the cultivation of sorghum and cowpea in association occupies an important place in agriculture and contributes to achieving food and nutritional security in the country. Cowpea is an important source of vegetable protein. This crop is faced with many biotic (insects) and abiotic (drought) problems. The attack of pests (insects) can completely reduce the production of cowpea. Most farmers use chemicals to reduce these pests. While these chemicals (insecticides) have a negative impact on human health and that of the ecosystem. Aphids (Aphis craccivora) and Marucas (Maruca vitrata) can cause yield losses of up to 80%. Finding alternatives to synthetic pesticides is therefore a major challenge for the design of cropping systems. The study was carried out at the Sotuba agronomic research station for two years. Three varieties of cowpea (Sangaranka, dijuifa and Ghana Shoba) were planted in split plot in pure culture and in association with sorghum (Tiandougou coura). Three (3) products (Azadiracta indica and Cassia nigricans leaf, Carapa procera oil) and two controls (optimal K and without treatment) were used against Aphis craccivora and Maruca vitrata of cowpea. Observations focused on the number of Maruca vitrata and Aphis craccivora colonies before and after each treatment, the weight (pod, grain, haulm). The data was analyzed with GENSTAT Release 12.1 of the 12th edition of 2012. Zarama(Cassia nigricans) extract was the most effective among the others after the first treatment on Aphis and Maruca with a count average of 1.44 and 1.33 respectively of these two insects. The best grain yield was recorded in the same Sangaraka variety (1623 kg.ha-1) by treatment with Neem extract (Azadiracta indica), i.e. an increase of 8.1%.

Keywords: Cowpea, Efficacy, Extracts, Plants, Insects.

### **1. INTRODUCTION**

Cowpea Vigna unguiculata L. Walpers (Fabaceae) is one of the main seed legumes produced and consumed in the world and particularly in West Africa, specifically in Mali (Théodore et al. 2022). Cowpea is native to West Africa and in Mali, it occupies a prominent place in human nutrition. It contributes to improving the nutritional quality of food for the urban and rural

Vol. 08, No. 04; 2023

#### ISSN: 2456-8643

population. Its role is known in livestock farming, from where it makes it possible to create fodder reserves for livestock during critical periods of lean season or prolonged drought in the semi-arid areas of West Africa (AGUIDI, TAMÒ, and AGBAKA 2013). Due to its role as soil fertiliser, its involvement in fodder (FOFANA, and COULIBALY, 2016). Cowpea, considered as a dual-purpose plant (grain and fodder), has significant nutritional, economic and socio-cultural importance.

It is an essential and inexpensive source of protein compared to that of animals. These young leaves, green pods and seeds are used in the preparation of a variety of foods in both rural and urban settings (Johnson et al. 2009). Recognized as the meat of the poor because its protein content (22-25%) is 2-3 times higher than cereals (Johnson et al. 2009). Globally, out of more than twenty million tons of cowpea produced, concerning Africa and mainly West Africa provides 82.3% (FAOSTAT, 2009).

In Mali in 2020 over an area of 406,698 ha, cowpea production was 199,763 tonnes with 491.2 kg/ha. (FAOSTAT, 2022). This production is affected by many biotic (insects) and abiotic (drought) problems. The attack of pests (insects) can totally reduce the production of cowpea. Farmers use more chemicals. While the excessive use of chemicals has negative impacts on human health and the environment. The ancestral knowledge of controlling these pests in an ecological way can be exploited to minimize the use and impact of chemicals. The use of plant extracts can be a solution to reduce the use of these chemicals in order to sustainably preserve human and environmental health. The objective was to improve grain and haulm yields under the effectiveness of plant extracts on cowpea pests in two cropping systems.

#### 2. MATERIAL AND METHODS

#### 2.1. Study environment

The study was conducted for two years (2021 and 2022) at the Regional Center for Agronomic Research (CRRA) in Sotuba, which is one of the six Regional Research Centers of the Institute of Rural Economy (IER). The CRRA of Sotuba is located in Commune I of the District of Bamako, about 7 km from the city center of Bamako at a latitude 12° 39' north, longitude 07° 56' west at an altitude of 320 m. It covers an area of 270 ha. It is bordered to the west by the industrial zone, to the east by the village of Sotuba, to the south by the Niger River and to the north by the Bamako-Koulikoro road which separates it from Boulkassoumbougou.

### 2.2. plant material

Three dual-purpose cowpea varieties (Sankaraga, Djiguifa, Ghana shoba) were planted in association with the Tiandougoucoura sorghum variety. Extracts of three plants (Cassia nigricans, Carapa procera, Azadiracta indica) plus optimal K as a control were used to treat cowpeas.

### 2.3. Methods

The objective of this activity is to preserve the production potential of dual-purpose cowpea and sorghum in an association system. The trial was implemented in a split-split-plot in three repetitions with three factors. The main factor was the two-level cropping system (association with sorghum, pure cowpea), the second factor was the 3-level genotype (3 varieties of cowpea: Sangaraka, Djiguifa, Ghana shoba), and the third factor was is the 5-level treatment product (Cassia nigricans powder, Azadiracta indica leaves, Carapa procera oil, optimal K and without treatment).

### **Implementation of the tests:**

The elementary plot was 5 m/ 8 lines corresponding to 30 m2. Sorghum is sown at spacings of 0.75 m x 0.50 m and cowpea 0.75 m x 1 m.

Vol. 08, No. 04; 2023

ISSN: 2456-8643

Organic manure (Profeba) was applied at a rate of 1 t ha-1 and 45 kg ha-1 at sowing and cereal complexes (17–17–17) two weeks after sowing.

#### Cassia nigricans

Commonly called Zarama in the local Mianga language, the whole plant without its roots was harvested, ground, dried in the shade for a week. After drying, the ground material is crushed by a mill to make it into a powder. The preparation of the spray is made with a dose of 250g of powder per 10 L left in maceration for 24 hours before application.

#### • Azadiracta indica,

Five kg of fresh Neem leaves (Azadiracta indica) were chopped and soaked in 10L of water for 24 hours then filtered before application.

#### • Carapa procera

Called Cobi in the local Bambara language whose oil is extracted from its nuts. The traditionally refined oil was obtained from the local market. It is mixed with water (15mL/10L of water) to treat 400m2.

The optimal K control was used at a dose of 1 L.ha-1.

The different products were sprayed using the Technoma 15 device.

#### • Plant spraying operation:

The treatment threshold is the presence of at least one colony of 5 insects on 5 different plants on the diagonal of the plot. The spraying was done at a frequency of 15 days apart, due to 10 liters for 400m2.

### • Comments

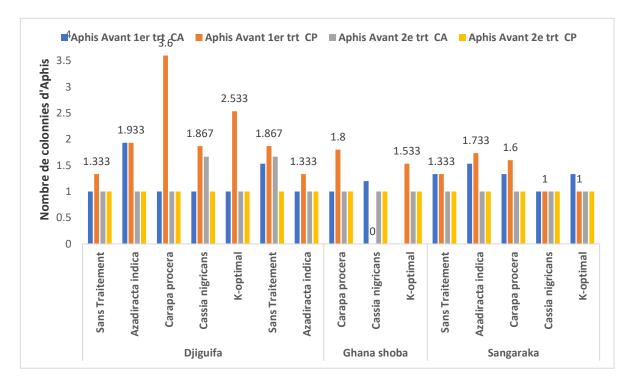

The ratings focused on the number of insects per elementary plot, insect damage to leaves, flowers and pods. The targeted insects were Aphiscraccivora, Marucavitrata.

### **3. RESULTS**

Figure 1 shows the number of Aphis colonies was higher before the first treatment (44 DAS) in pure culture than in association, the maximum of which was recorded with Carapa procera (3.6) in the Djiguifa plot. This number of colonies fell before the second treatment (58 DAS) in pure culture than in association with all the plant extracts in the three varieties of cowpea (Sangaraka, Djiguifa, Ghana shoba).

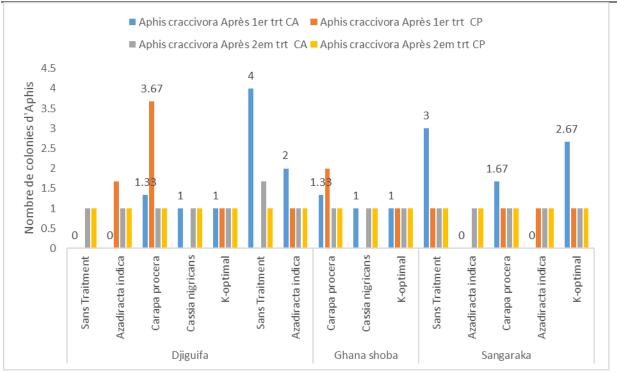

**Figure 1:** Number of colonies of Aphis craccivora in the first year (2021) before the first (44 DAS) and the second treatment (58 DAS)

NB: CA: culture in association. CP: pure cowpea crop.

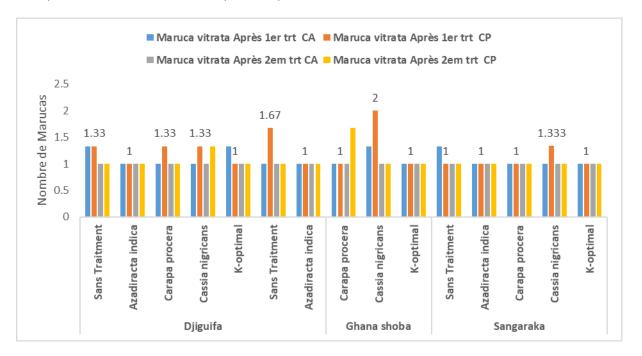

The maximum number(4) of colonies of Aphis craccivora recorded after the first treatment (48 DAS) in the control plot without treatment in intercropping with the Ghana shoba variety against 3.67 in pure cowpea culture treated with C. procera in the Djiguifa variety. The presence of Aphids was almost zero after the second treatment (Figure 2).

ISSN: 2456-8643

**Figure 3:** Number of Maruca vitrata in the first year (2021) after the first (48 DAS) and the second treatment (62 DAS)

Before the first treatment (44 DAS) and the second treatment (58 DAS), there was no significant difference for the parameters studied in relation to the number of Aphis; the Maruca was only seen before the second treatment. (Table 1)

Statistical analysis showed highly significant differences (P<0.01) in 2022 between treatments for pod and grain yield. It was significant for dry and fresh haulm yield (table 4). In association, the Sangaraka variety recorded the grain yield (1645 kg.ha-1) with the treatment of the K-optimal control followed by the treatment of the Cassia nigricans extract (987 kg.ha-1). On the other hand in culture pure the best grain yield was recorded in the same variety Sangaraka (1623)

Vol. 08, No. 04; 2023

With a highly significant difference between the genotypes, Sangaraka recorded the best pod and grain yield with 1741 kg ha-1 and 961 kg ha-1 respectively (Table 5). Between the treatment products also including the Neem extract after the optimal K control recorded an average of 1203 kg ha-1 and 671 kg ha-1 for the pod and grain yield. The interaction of the three studied factors recorded a highly significant difference for pod and grain yield.

 Table 5: Overall averages and probabilities of cropping system, genotypes, treatments and interactions in 2022

### 4. DISCUSSION

Plant extracts revealed a different effect on cowpea arthropods in association with sorghum and in pure culture. (AKOUDJIN, DABIRE, and SOMDA 2023) demonstrated that the abundance of insects was higher in untreated control plots compared to plots treated with Neem extracts (A. indica).

Vol. 08, No. 04; 2023

#### ISSN: 2456-8643

Treatment with plant extracts can increase the yield of cowpea while reducing the number of insects depending on the year, which has been demonstrated by (Abdoulaye Zakari 2020) who confirms that the Neem extract at a dose of 5% had a increase of 985 Kg/ha.

Association cowpea/sorghum reduces the number of Aphis craccivora and Maruca vitrata compared to the pure culture of cowpea. This was justified by (Corre-Hellou et al. 2014) in a plot, the diversity of cultivated plants can significantly influence the abundance of phytophagous crop pests, compared to a single specific crop.

Dual-purpose cowpea and sorghum in combination improve soil fertility while increasing production as demonstrated by Obulbiga et al, 2015). The grain yield of dual-purpose cowpea varieties varied according to the varieties tested, which was confirmed by Saidou et al. 2018.

Treatment with plant extracts in the field can increase the yield of cowpea (985 Kg.ha-1) while reducing the number of insects depending on the year, which has been demonstrated by (Abdoulaye Zakari 2020) who confirms that the extract of Neem (A.indica) at 5% dose had a considerable increase in cowpea yield. This was confirmed by (Harouna et al. 2019) who found a yield increase ranging from 811 to 1233 kg.ha-1.

#### 5. CONCLUSION

An improvement in grain and haulm yields was observed through the use of plant extracts, particularly Neem leaves (Azadiracta indica) during the two years of study.

The use of plant extracts on cowpea pests in both cropping systems was effective while reducing their number. The effects and abundance of insects can vary according to the years of culture of cowpea in association than in pure culture.

The number of insect populations is generally higher in pure cowpea culture than in combination, this demonstrates the positive effect of biopesticide products and the sorghum/cowpea cropping system on the insect populations observed. These numbers generally decrease as the treatment progresses with the products.
